19. ABSTRACT (Continue on reverse if necessary and identify by block number) The ground state of a two-dimensional charged-boson system is investigated over the range of densities $1 \leq R_s \leq 10$ in the self-consistent field approximation; $R_s = (a^2 \pi \rho)^{-1/2}$, where a_0 is the Bohr radius and ρ is the number density. Starting with numerical self-consistent calculations of the static structure factor, the elementary excitation, pair-correlation functions, pressure and ground-state energy are evaluated. These results are compared with those of the two-dimensional and three-dimensional systems obtained from other methods. The ground-state energy is given as $E_0 = -1.2918 R_s^{-2/3} + 0.03$, which improves the result from the ring-diagram approximation.

Acknowledgments

This work was supported in part by the Dai-Woo Foundation and in part by the U. S. Office of Naval Research.

and for the 3D charged-boson system the ground-state energy per particle is evaluated by various methods:

$$E_0 = - 0.8030 R_s^{-3/4} , \quad (\text{RDA})^{19} \quad (4.3)$$

$$E_0 = - 0.8030 R_s^{-3/4} + 0.027 , \quad (\text{VCA})^5 \quad (4.4)$$

$$E_0 = - 0.8030 R_s^{-3/4} + 0.032 . \quad (\text{SCFA})^8 \quad (4.5)$$

The extra numerical terms in Eqs. (4.2), (4.4) and (4.5) are due to the better estimation of the correlation. The numerical data for the ground-state energies in the various calculations are summarized in Table 1, where we see that the SCFA results are an improvement over the RDA results.

Differentiating Eq. (3.20) with respect to R_s , we obtain the pressure of the 2D charged-boson system:

$$\frac{P}{\rho} = - \frac{R_s}{2} \frac{dE_0}{dR_s} . \quad (4.6)$$

The numerical results for the pressure are listed in Table 2 in comparison with the RDA results.

In conclusion, we remark that the behaviors of the elementary excitation spectrum, structure factor and pair-correlation functions obtained from the SCFA, which includes the short range correlations for the 2D charged-boson system, are very much like those of the 3D case. The SCFA results for the ground-state energy are an improvement over the RDA results.

factor increases more slowly than the 3D structure factor in the short-wavelength region but more quickly in the long-wavelength region as qr_0 is varied.

With the use of the above calculations for the structure factor, we evaluate the pair-correlation function from Eq. (3.13). The result is given and compared with the 3D case in Fig. 4. The pair-correlation function starts oscillating at large distances, which is not displayed in the figures. These oscillations have very small and broad amplitudes. This long-distance behavior is similar to the 3D case. For Bose fluids¹⁸ interacting via a soft potential with a Lennard-Jones type tail and pseudopotential, in the RDA the pair-distribution functions become negative at short distances and decrease as r^{-3} at large distances. This decrease corresponds to the existence of a phonon spectrum for small momenta. In the RDA the pair-distribution function for the 2D charged boson becomes negative with decreasing R_s and diverges at $r \rightarrow 0$. Consideration of the short-range correlation of the charged boson through the local-field correction SCFA improves the result from the RDA, i.e., the value of $g(0)$ obtained in SCFA is negative, but so small that for the practical purposes one can consider $g(0)$ to be zero.

We have evaluated the ground-state energy by a numerical self-consistent solution through Eqs. (3.14) and (3.19) to give

$$E_0 = - 1.2918 R_s^{-2/3} + 0.03 \quad . \quad (4.1)$$

In the RDA we have obtained the ground-state energy per particle in terms of R_s as

$$E_0 = - 1.2918 R_s^{-2/3} \quad , \quad (4.2)$$

$$E_0 = 2^{1/3} R_s^{-2/3} \int_0^1 d\alpha \int dq [S(\alpha, q) - 1] \quad (3.20)$$

We note that the 3D ground-state energy per particle in Rydbergs is given by

$$E_0 = \frac{2}{\pi} 3^{1/4} R_s^{-3/4} \int_0^1 d\alpha \int_0^\infty dq [S(\alpha, q) - 1] \quad (3.21)$$

4. Results and discussion

In the previous sections we have evaluated the elementary excitation spectrum, pair-correlation functions and the ground-state energy of the charged-boson system from the determination of the structure factor in the self-consistent field approximation. Figure 1 illustrates the elementary excitation spectrum as a function of qr_0 for various values of R_s . We see that the third term in the bracket of Eq. (3.10) is dominant in the high-momentum region, and thus the excitation energy is almost identical with that of a free-particle. As R_s increases the excitation energy reduces more rapidly to the free particle case. We notice that in the low-momentum region the 3D excitation energy obtained from the SCFA decreases as q increases, and this reduction is quite significant with increasing R_s . This reduction does not appear in the 2D case for the range of densities $1 \leq R_s \leq 10$. A comparison of Eqs. (3.6) and (3.12) shows that the result in the SCFA gives a correction to Eq. (3.12) derived from the RDA.

In Fig. 2 we have given the numerical calculation of Eq. (3.14) as a function of qr_0 for various values of R_s by the iteration method. The structure factor converges very rapidly to unity as R_s increases. We have compared the 2D structure factor to the 3D case in Fig. 3. The 2D structure

by the method of iteration. The 3D structure factor⁸ in the long-wavelength approximation is given by

$$S(\vec{q}) = \left[1 + \frac{12}{R_s^2 q^4} (1 - \gamma q^2) \right]^{-1/2}, \quad (3.16)$$

with

$$\gamma = - \frac{2R_s^3}{9\pi} \int_0^\infty dq [S(\vec{q}) - 1]. \quad (3.17)$$

Comparing Eqs. (3.9) and Eq. (3.17), we find that both forms are similar to each other, with dependence of the spatial dimensionality on the dimensionless parameter R_s .

From the pair-correlation function or structure factor, we can calculate the ground-state energy of the charged-boson system. We may write the interaction energy as

$$E_{\text{int}}(\alpha) = \pi N \rho \int_0^\infty dr \phi(r, \alpha) [g(r) - 1] r, \quad (3.18)$$

or

$$E_{\text{int}}(\alpha) = \frac{N}{2} \int_0^\infty dq \alpha [S(\alpha, \vec{q}) - 1]. \quad (3.19)$$

Expressing the wave number and the density in units of $(2\pi\rho a_0^2)^{1/2}$ and R_s , we can write the ground-state energy per particle in Rydbergs as

$$E(\vec{q}) = \hbar\Omega(1 + \frac{\hbar^2 q^4}{2m^2 \Omega^2}) \quad (3.12)$$

The short-range correlation functions occurring in the Coulomb interaction between the charged bosons are expressed by the pair-correlation function $g(r)$, which represents the probability of finding two boson particles separated by a distance r . The inverse Fourier transform of the structure factor yields

$$g(r) = 1 + \frac{R_s^2}{2} \int dq \, q \, J_0(qr) [S(\vec{q}) - 1] \quad (3.13)$$

and from Eqs. (2.4), (2.7) and (3.6) the structure factor becomes

$$S(\vec{q}) = (1 + \frac{8}{R_s^2 q^3} [1 - G(\vec{q})])^{-1/2} \quad (3.14)$$

with

$$G(\vec{q}) = \frac{R_s^2}{\pi} \left\{ \int_0^q dk \, k E(\frac{k}{q}) [S(k) - 1] + q \int_q^\infty dk ([1 - (\frac{k}{q})^2] K(\frac{k}{q}) + (\frac{k}{q})^2 E(\frac{k}{q})) [S(k) - 1] \right\} \quad (3.15)$$

where r , q and k are expressed in units of the Bohr radius a_0 and a_0^{-1} , respectively, and $K(x)$ and $E(x)$ are the complete elliptic integrals of the first and second kinds. The numerical solution of Eq. (3.14) can be obtained

$$S(\vec{q} - \vec{k}) = S(\vec{q}) - q \cos \theta \frac{\partial S(k)}{\partial k} + \dots, \quad (3.7)$$

the local field correction $G(\vec{q})$ becomes

$$G(\vec{q}) = \gamma q \quad (3.8)$$

and

$$\gamma = - \frac{R_s^2}{4} \int_0^\infty d^2 q [S(\vec{q}) - 1] \quad (3.9)$$

Then the excitation spectrum can be expressed as

$$E(\vec{q}) = \hbar \Omega \left[1 - \frac{\gamma}{2} q + \frac{\hbar^2 q^4}{8 m^2 \Omega^2} \right] \quad (3.10)$$

where $\Omega = (2\pi\rho e^2/m)^{1/2}$ is the two-dimensional plasma frequency. In the case of three-dimensions the excitation spectrum in the long-wavelength approximation is given by

$$E(\vec{q}) = \hbar \omega_p \left[1 - \frac{\gamma}{2} q + \frac{\hbar^2 q^4}{2 m^2 \omega_p^2} \right] \quad (3.11)$$

where $\omega_p = (4\pi\rho e^2/m)^{1/2}$ is the 3D plasma frequency. We remark that one of the authors has obtained the excitation spectrum of the 2D charged-boson system through the RDA in the long-wavelength approximation as¹⁷

where $\lambda^3 = 8\pi\rho/a_0$. The total induced charge Q is

$$\begin{aligned}
 Q &= -e \int d^2r \delta\rho(\vec{r}) \\
 &= ze \int d^2q \frac{\sin(qr)}{G(\vec{q}) - (\frac{q}{\lambda})^3 - 1} = -ze \quad .
 \end{aligned}
 \tag{3.4}$$

Equation (3.4) indicates that the charged impurity is completely screened at long distances. However, the induced charge density [Eq. (3.3)] diverges at $r = 0$. This divergence is due to the fact that the linearized equation of motion for the classical one-particle distribution function is invalid near the charged impurity. The divergence can be avoided by taking quantum effects into consideration.

The elementary excitation spectrum $E(\vec{q})$ is determined from the pole of the density-density response function $\chi(\vec{q}, \omega)$, which yields

$$[\omega(\vec{q}) + i\eta]^2 - \epsilon^2(q) - 2\rho\epsilon(\vec{q})\psi(\vec{q}) = 0 \quad , \tag{3.5}$$

and thus the excitation energy $E(\vec{q}) = \hbar\omega(\vec{q})$ can also be written as

$$E(\vec{q}) = [\epsilon(\vec{q})^2 + 2\rho\epsilon(\vec{q})\psi(\vec{q})]^{1/2} \quad . \tag{3.6}$$

We notice that the elementary excitation spectrum in the ring-diagram approximation (RDA)¹⁶ can be obtained under the condition $\psi(\vec{q}) = \phi(\vec{q})$, i.e., the neglect of the local corrections in Eq. (3.6). Making use of the following expression for the structure in the long-wavelength approximation,

We find the ground-state energy to be

$$E_0 = \int_0^{e^2} \frac{d\alpha}{\alpha} E_{\text{int}}(\alpha) \quad , \quad (2.8)$$

where $E_{\text{int}}(\alpha)$ is the interaction energy as a function of the coupling constant α which is a measure of the strength of the coupling between bosons.

3. Excitation Spectrum, Structure Factor, Correlation Function and Ground-State Energy

We first investigate the response of the charged-boson system to a static impurity with charge ze located at the origin, where the external potential is

$$\phi_{\text{ext}}(\vec{q}, \omega) = \frac{4\pi^2 ze}{q} \delta(\omega) \quad . \quad (3.1)$$

The induced charged density, which characterizes the linear response to an external potential from a fixed charge, can be written as

$$\delta\rho(\vec{q}, \omega) = -\chi(\vec{q}, \omega) e\phi_{\text{ext}}(\vec{q}, \omega) \quad . \quad (3.2)$$

Through the inverse Fourier transform of Eq. (3.2), we obtain the induced charge density at position \vec{r} as

$$\delta\rho(\vec{r}) = -\frac{z}{2\pi r} \int_0^\infty dq \frac{\sin(qr)}{G(\vec{q}) - \left(\frac{q}{\lambda}\right)^3 - 1} \quad , \quad (3.3)$$

In Eq. (2.2), $\chi_0(\vec{q}, \omega)$ is the density-density response function for a noninteracting charged-boson system at $T = 0$ given as

$$\chi_0(\vec{q}, \omega) = 2\rho\epsilon(\vec{q})/[(\omega + i\eta)^2 - \epsilon(\vec{q})^2] \quad , \quad (2.3)$$

where $\epsilon(\vec{q}) = \hbar^2 q^2/2m$ is the free particle energy, η is a positive infinitesimal quantity, and $\psi(\vec{q})$ is the self-consistent effective potential,

$$\psi(\vec{q}) = \phi(\vec{q})[1 - G(\vec{q})] \quad . \quad (2.4)$$

Here, $\phi(\vec{q}) = 2\pi e^2/q$ is the two-dimensional Fourier transform of the Coulomb interaction e^2/r , and $G(\vec{q})$ is given by

$$G(\vec{q}) = -\frac{1}{\rho} \int \frac{\vec{q} \cdot \vec{k}}{qk} [S(\vec{q} - \vec{k}) - 1] \frac{d^2 k}{(2\pi)^2} \quad . \quad (2.5)$$

In Eq. (2.5) the static structure factor $S(\vec{q})$, which is the Fourier transform of the pair-correlation function $g(r)$, can be expressed as

$$S(\vec{k}) = 1 + \rho \int d^2 r [g(r) - 1] e^{-i\vec{k} \cdot \vec{r}} \quad . \quad (2.6)$$

The singularities of the density-density response function represent the energies of the excited states, and the excitation energy of the system is related to $S(\vec{q})$ through the Feynman expression

$$E(\vec{q}) = \epsilon(\vec{q})/S(\vec{q}) \quad . \quad (2.7)$$

spectrum, structure factor, pair-correlation function and the GSE of 2D charged-boson systems. Therefore, in this paper we evaluate the above quantities of a 2D charged boson system, which consists of N identical bosons with charge e and mass m , interacting via a Coulomb potential at $T = 0$ over the range of densities $1 \leq R_s \leq 10$. To calculate the above quantities we adopt the SCFA given by Singwi et al. We survey the basic formula in Sec. 2, and starting with the numerical self-consistent evaluation of the static structure factor $S(\vec{q})$, we obtain the elementary excitation spectrum, correlation function and ground-state energy in Sec. 3. Finally, in Sec. 4 we present our numerical results for the above quantities in comparison with other works in terms of graphs and tables.

2. Basic Formulas

The self-consistent field approximation in the formalism of Singwi et al includes the decoupling of the two-particle distribution function in the Liouville equation into the product of two one-particle distribution functions and a pair-correlation function,

$$f(\vec{r}, \vec{p}, \vec{r}', \vec{p}', t) = f_1(\vec{r}, \vec{p} | t) f_1(\vec{r}', \vec{p}' | t) g(\vec{r} - \vec{r}') \quad , \quad (2.1)$$

where \vec{r} and \vec{p} are the position and momentum of each particle and $g(r)$ represents the equilibrium static pair-correlation function. The density-density response function $\chi(\vec{q}, \omega)$ in Fourier space for an interacting system becomes

$$\chi(\vec{q}, \omega) = \chi_0(\vec{q}, \omega) / [1 - \psi(\vec{q}) \chi_0(\vec{q}, \omega)] \quad . \quad (2.2)$$

1. Introduction

Since Foldy's pioneering work¹ on the charged-boson system, there has been continuing interest in this system from the view point of real physical systems.² It should be pointed out that the special characteristic shared by the charged boson and electron gas is that the properties of the ground state can be described by only a single dimensionless parameter $R_s = r_0/a_0$, where $r_0 = (\pi\rho)^{-1/2}$ is the mean particle distance, ρ is the number density, and $a_0 = \hbar^2/me^2$ is the Bohr radius of the particle with mass m . The electron gas has been widely investigated for its applications to metals. However, the charged-boson system has been largely ignored because of its nonexistence.

Concerning the ground-state energy (GSE), Foldy first calculated the GSE and elementary excitation spectrum of the charged boson system in the high density region ($R_s \leq 1$), which was also later evaluated by others.³ In the intermediate density region ($1 \leq R_s \leq 100$), Lee,⁴ Lee and Ree⁵ and Monnier⁶ evaluated the GSE through the variational method with a Jastrow trial wave function. More recently Hansen and Maxighi⁷ obtained a variational upper bound to the GSE over a wide range of densities ($1 \leq R_s \leq 200$) with the use of a variational Jastrow trial wave function, the hypernetted chain integral equation, and the Monte Carlo method, and Hipolito et al.⁸ investigated the dielectric properties and also the two-dimensional (2D) and three-dimensional (3D) classical electron systems by adopting the self-consistent field approximation (SCFA) introduced by Singwi et al.⁹

Although, in the past two decades, significant progress has been made in the study of the 2D electron systems for the dielectric function, structure factor and pair-correlation function,¹⁰ GSE and specific heat,¹¹ effective mass,¹² superlattice,¹³ quantized Hall effect¹⁴ and other quantities,¹⁵ there is much less information about the properties of the elementary excitation

Ground state of a two-dimensional charged-boson system

The ground state of a two-dimensional charged-boson system is investigated over the range of densities $1 \leq R_s \leq 10$ in the self-consistent field approximation; $R_s = (a_0^2 \pi \rho)^{-1/2}$, where a_0 is the Bohr radius and ρ is the number density. Starting with numerical self-consistent calculations of the static structure factor, the elementary excitation, pair-correlation functions, pressure and ground-state energy are evaluated. These results are compared with those of the two-dimensional and three-dimensional systems obtained from other methods. The ground-state energy is given as $E_0 = -1.2918 R_s^{-2/3} + 0.03$, which improves the result from the ring-diagram approximation.
